ARTICLE INFO

Abstract

Colorectal cancer is the third most prevalent cancer and the second most frequent cause of cancer-related death in the world. Surgical resection of the primary tumor is the central aspect of the current multiple modes of treatment and has been associated with better prognosis. The process of surgery, including anesthetic regimens, has increasingly been recognized to affect colon cancer recurrence and metastasis. Both retrospective clinical studies and laboratory studies have reported that colon cancer cells are inhibited by some local anesthetics. However, the application of local anesthetics in colon cancer treatment is limited by our understanding of the mechanisms underlying their effects on cancer biology. Local anesthetics have been proved to preferentially inhibit cancer stem cells which imply that local anesthetics target colon cancer stem cell to suppress cancer progressing. Here this paper will review and propose several potential studies, including using colon cancer cell lines and animal models to test the effect of local anesthetics on population, viability, and migration of colon cancer stem-like cell, and screen and search for potential molecular targets underlying these effects.

Mini Review

Colorectal cancer is the third most prevalent cancer and the second most frequent cause of cancer-related death in the world., Surgical resection of the primary tumor is the central aspect of the current multiple modes of treatment and has been associated with better prognosis. However, metastasis is the dominant cause of death in patients with colon cancer. On top of cell migration, chemokines have been implicated in additional aspects of malignant transformation, such as proliferation, survival, and angiogenesis. The process of surgery, including anesthetic regimens, has increasingly been recognized to affect colon cancer recurrence and metastasis. Retrospective clinical studies have suggested that the use of regional anesthesia leads to improved patient outcomes., Laboratory studies have reported that colon cancer cells are inhibited by some local anesthetics. However, the application of local anesthetics in colon cancer treatment is limited by our understanding of the mechanisms underlying their effects on cancer biology. Emerging evidence has indicated a subpopulation of stem-like cells within tumors, known as CSCs, which contribute to cancer treatment failure and cancer relapse. ,

The cancer stem cell hypothesis is rising to be an attractive cellular mechanism that proposes a hierarchical organization within the colon tumor bulk and justifies the functional heterogeneity of solid tumors responsible for the aggressive nature of the malignancy and therapeutic refractoriness [1-10].

Amide-linked local anesthetics, lidocaine, ropivacaine, and bupivacaine, have been proved to preferentially inhibit colony formation and self-renewal of cancer stem cells. A recent study also showed that local anesthetics inhibit colon cancer not through inducing apoptosis or damaging the cell (cytotoxicity) but through arresting cell proliferation cycle. These conclusions imply that local anesthetics target colon cancer stem-like cell to suppress cancer progressing. We aim to determine the effect of local anesthetics on population, viability, and migration of colon cancer stem-like cell, and screen and search for potential molecular targets underlying these effects. The information about their potency and efficacy against colon cancer stem-like cells and the potential targets would help explain the mechanism of effect of regional anesthesia on colon cancer [11-24].

Hypothesis and Potential Research in This Field

a) Here, based on previous knowledge and studies, this review proposed a hypothesis that local anesthetics target colon cancer stem cell to suppress cancer progressing. There are several aspects that can be explored: To explore the effects of local anesthetics on colon cancer stem-like cells.

b) To explore the effects of local anesthetics on colon cancer stem-like cell in a murine cancer model.

c) To explore the effects of local anesthetics on the stem-like cell population in clinical colon cancer tissue.

d) To explore the potential stemness-correlate molecular mechanism underlying the effect.

Potential Available Methods and Strategies

This review proposed several potential available Methods and strategies.

The Sorting of Stem-Like Cell Subpopulation

Immuno-magnetic cell sorting of stem cell subpopulation will be used. Human colorectal carcinoma cell lines HCT116, SW480 and HT29 will be exposed to FITC-conjugated anti-CD44, anti-ALDH, and anti-LGR5 antibody, and further labeled with dextran-coated magnetic nanoparticles using bispecific Tetrameric Antibody Complexes (TAC). These cells will be subjected to immuno-magnetic cell separation and CD44+, ALDH+, and LGR5+ cells will be identified as cancer stem cells. Sphere culture will also be used as another method to extract cancer stem-like cells. Cells will be cultured in ultralow attachment plates and the sphere passage cells will be identified as cancer stem cells.

The Effects of Local Anesthetics on Colon Cancer Stem-Like Cell

The colon cancer cell lines and cancer stem-like cell line (sorted cancer cell line derived cells) will be used to test the effects of local amide-linked local anesthetics (lidocaine, ropivacaine, and bupivacaine). Local anesthetics have a wide range of uses in clinical practice and their plasma concentrations can vary widely and the peak plasma concentrations ranging between 1 and 3μM., Clinically relevant concentrations will be used to treat the cell. 1, 2, 4, 12, 24, 48, and 72h will be set as treatment time. Cell viability, migration, invasion, and adhesion of cell lines will be determined using MTT, Cell Cytotoxicity Assay Kit, apoptosis ELISA Kit, Flow Cytometry, wound healing, trans well, matrices assay, colony-forming assay, trypsin detaching assay, etc. Self-renewal ability of cell lines will be determined using serial replating assays. The population of cancer stem-like cells in HCT116 and HT29 will be determined by cancer stem cell markers stain using the Immunohistochemistry and Flow Cytometry method.

The Effects of Local Anesthetics on Colon Cancer Stem-Like Cell in A Murine Colon Cancer Model

Immunodeficient NSG mouse model with implantation of green fluorescent protein-labeled colon cancer cells (HT29) and cancer stem-like cells (HT29 sorted by the method described previously) will be used. In the long-term treatment group, the primary tumor will be treated with clinically relevant concentration local perfusion of local anesthetics per day, while in the short-term treatment group, the animals will only be treated during the surgery. Tumor development will be monitored through longitudinal magnetic resonance imaging-based morphometric analysis and survival. Established serum markers of tumor spread will be measured serially and circulating tumor cells will be detected via fluorescence measurements. The primary tumor will be excised and collected after four weeks and the primary recurrent tumor and metastatic tissue (lung, brain, bone, etc.) will be collected. The population of cancer stem-like cell and in tumor and metastatic tissue will be determined by markers stain using Immunohistochemistry method.

The Effects of Local Anesthetics on The Stem-Like Cell Population in Clinical Colon Cancer Tissue

To determine whether local anesthetics can decrease colon cancer stem-like cell population in cancer tissue from patients, the colon cancer tissues with complete clinical pathological data will be collected from patients with and without lidocaine treatment. The Paraffin-embedded tissue microarray was constructed and the cancer stem-like cell population in cancer tissue will be determined by cancer stem cell markers, (CD44+, CD24−/low, ALDH+ and LGR5+) stain using the Immunohistochemistry method.

The Effect of Local Anesthetics on Stemness-Correlate Molecular Features

The colon cancer cell lines and cancer stem-like cell line will be treated with local anesthetics. Total protein and total RNA of cells will be extracted, and proteomic analysis and gene array method will be used to screen altered protein and gene expression. QPCR, Immunofluorescence stain, Western blot, and Immunohistochemistry methods will be used to confirm the results. Gene-knock-out method will be used to test the potential targets of local anesthetics involved in stemness-correlate signal.

Conclusion

This study hopes to emerge with a detailed clarification of the effect of local anesthetics on population, viability, and migration of colon cancer stem-like cell and specific molecular targets underlying these effects, and in turn, deepen our understanding of local anesthetics in colon cancer treatments. Here, this review proposed that

a)   Colon cancer stem-like cells will be identified and sorted out of colon cancer cell lines.

b)   Local anesthetics can suppress viability, migration, invasion, and adhesion more in colon cancer stem-like cell line than in colon cancer cell lines. The population of colon cancer stem-like cell in colon cancer cell lines will decrease after treating with local anesthetics.

c)   The population of colon cancer stem-like cell in tumor and metastatic tissue will decrease and cancer progression will be suppressed in local anesthetics treatment groups.

d)   The tumor tissue from patients with local anesthetics treatment has less cancer stem-like cells.

e)   Several targets of Local anesthetics will be identified. Advantageous molecular targets of stemness will be suppressed and disadvantageous targets of stemness will be promoted in colon cancer cells. Knocking out/down these targets can block the effects of the local anesthetics.
